BROWN MIDRIB SORGHUM-SUDANGRASS - TASTES BETTER, LESS FILLING

Keith Johnson
Forage Crops Specialist
Agronomy Department, Purdue University

What is a "midrib"? Most grass plants have a very obvious vein in the leaf blade that extends from the base of the leaf to its tip. This vein is called a midrib. What is the significance of the color brown? Grass midribs are typically a whitish green color. Mutations of corn, sorghum and pearl millet have been identified that result in a brown midrib. The significance of the mutation is that plant tissues have less lignin than normal tissues. The brown color is also obvious in the stem, especially in cross section. What is lignin? Lignin is a compound with no predetermined order. It is formed with multiple reactions involving phenolic compounds (hydroxyl derivatives of aromatic hydrocarbons). It forms covalent cross-linkages with hemicellulose, but not with cellulose. These three compounds, hemicellulose, cellulose, and lignin, are the components of plant cell walls. Why is lignin important? Lignin content increases as a plant matures and is thought to provide the structure necessary to help a plant grow erect. Whereas lignin might hold a plant erect, too much lignin results in less intake by the consuming animal and reduced cell wall digestibility. The mutation associated with the brown midrib trait results in a change in enzyme activity associated with the process of lignin formation. Less lignin and the chemical attributes of lignin occur with the mutation. Brown midrib sorghums are available. Brown midrib corn hybrids have been available to the public for several years but have the constraint of reduced grain yield. Production Plus + Seeds, located in Plainview, TX, released 'NutriPlus BMR' brown midrib sorghum-sudangrass in 1996.

Since then they have released brown midrib forage sorghums. These sorghums do not have the negative issue associated with corn productivity (Mike Northcutt, personal communication). Improved Palatability Observed in 1998. Dry ewes had free choice pasture of Nutriplus BMR or a normal sorghum-sudangrass at the Purdue University Agronomy Research Center, West Lafayette, in 1998. I was impressed with how ewes would graze the lower stem of the brown midrib hybrid in preference to leaf tissue of a normal hybrid. These observations resulted in similar demonstrations being sown in 1999 at the 1) Beef and Sheep Units associated with the Animal Sciences Research and Education Center, 2) Feldun-Purdue Ag Center, and 3) the Agronomy Research Center. Differences in animal performance are also being conducted in 1999 with replacement heifers at Feldun-Purdue Ag Center and with beef cows-calves at the Southern IN Purdue Ag Center located near Dubois, IN. Where can seed be found in IN? Production

Plus + Seeds indicated that brown midrib sorghums are available from the following agribusinesses:

Ag Nation Products East Canton, OH 800-247-3276 to find closest IN distributor

AgriBioTech of Indiana Elwood, IN 800-886-3043

CISCO Indianapolis, IN 800-888-2986

Grazing Systems Supply & Griewe Seed Greensburg, IN 888-635-8588

TenBarge Seed, Inc. Haubstadt, IN 800-467-0158
